# Part I INTRODUCTION

1

#### MOTIVATION AND PROBLEM STATEMENT

Ranking is a core problem in the field of information retrieval. The ranking task in information retrieval entails the ranking of candidate documents according to their relevance for a given query. Ranking is useful in many other application domains outside information retrieval as well, amongst others in drug discovery and to determine the order of maintenance operations [42]. Learning-to-Rank has also been argued to be a more fitting approach to recommender systems than rating prediction [2, 35].

Research in the field of ranking models has for a long time been based on manually designed ranking functions and has been an active area of research. Luhn [33] was the first to propose a model that assigned relevance scores to documents given a query back in 1957. The increasing amounts of potential training data have recently made it possible to leverage machine learning methods to obtain more effective models. Learning-to-Rank is the relatively new research area that covers the use of machine learning models for the ranking task.

In recent years several Learning-to-Rank benchmark datasets have been proposed that enable comparison of the performance of different Learning-to-Rank methods. Well-known benchmark datasets include the *Yahoo! Learning to Rank Challenge* dataset [13], the Yandex Internet Mathematics competition<sup>1</sup>, and the LETOR dataset [40] that was build by Microsoft Research. One of the concluding observations of the *Yahoo! Learning to Rank Challenge* was that almost all work in the Learning-to-Rank field focuses on ranking accuracy, while efficiency and scalability of Learning-to-Rank algorithms is still an underexposed research area that is likely to become more important in the near future as training sets are becoming larger and larger [14]. Liu [30] confirms the observation that efficiency and scalability of Learning-to-Rank methods has so far been an overlooked research area in his influential book on Learning-to-Rank.

Some research has been done in the area of parallel or distributed machine learning [17, 12]. However, almost none of these studies include the Learning-to-Rank sub-field of machine learning. The field of efficient Learning-to-Rank has been getting some attention lately [3, 4, 10, 45, 43], since Liu [30] first stated its growing importance back in 2007. Only several of these studies [45, 43] have explored the

<sup>1</sup> http://imat-relpred.yandex.ru/en/

possibilities of efficient Learning-to-Rank through the use of parallel programming paradigms.

MapReduce [20] is a parallel programming framework that is inspired by the *Map* and *Reduce* functions commonly used in functional programming. Since Google developed the MapReduce parallel programming framework back in 2004 it has grown to be the industry standard model for parallel programming. Lin [29] observed that algorithms that are of iterative nature, which most Learning-to-Rank algorithms are, are not amenable to the MapReduce framework. Lin argued that as a solution to the non-amenability of iterative algorithms to the MapReduce framework, iterative algorithms can often be replaced with non-iterative alternatives or can still be optimized in such a way that its performance in a MapReduce setting is good enough.

The appearance of benchmark datasets gave insight in the performance of different Learning-to-Rank approaches, which resulted in increasing popularity of those methods that showed to perform well on one or more benchmark datasets. Up to now it remains unknown whether popular existing Learning-to-Rank methods scale well when they are used in a parallel manner using the MapReduce framework. This thesis aims to be an exploratory start in this little researched area of parallel Learning-to-Rank. A more extensive overview of my research goals and questions are described in chapter 2.

#### RESEARCH GOALS

The objective of this thesis is to explore the speed-up in execution time of Learning-to-Rank algorithms through parallelisation using the MapReduce framework. This work focuses on those Learning-to-Rank algorithms that have shown leading performance on relevant benchmark datasets. This thesis addresses the following research questions:

- RQ1 What are the best performing Learning-to-Rank algorithms on relevant benchmark datasets?
- RQ2 What is the speed-up of those Learning-to-Rank algorithms when executed using the MapReduce framework?

  Where the definition of *relative speed-up* is used for speed-up [46]:

```
S_N = \frac{\text{execution time using one core}}{\text{execution time using } N \text{ cores}}
```

RQ3 Can those Learning-to-Rank algorithms be adjusted in such a way that the parallel execution speed-up increases without decreasing accuracy?

#### APPROACH

A literature study will be performed to get insight in relevant existing techniques for large scale Learning-to-Rank. The literature study will be performed by using the following query:

• ("learning to rank" OR "learning-to-rank" OR "machine learned ranking") AND ("parallel" OR "distributed")

and the following bibliographic databases:

- Scopus
- Web of Science

The query incorporates different ways of writing of Learning-to-Rank, with and without hyphens, and the synonymous term *machine learned ranking* to increase search recall, i.e. to make sure that no relevant studies are missed. For the same reason the terms *parallel* and *distributed* are included in the search query. Even though *parallel* and *distributed* are not always synonymous is all definitions, we are interested in both approaches in non-sequential data processing.

To answer the first research question, I will implement Learning-to-Rank methods in the MapReduce framework and measure runtime as a factor of the number of cluster nodes used to complete the computation.

To implement the Learning-to-Rank algorithms, I will use cloud based MapReduce implementation from Microsoft was used that is called HDInsight. It which is based on the popular MapReduce open source implementation Hadoop<sup>1</sup>. The algorithms that we include in the measurements will be determined based on experimental results on the *Yahoo! Learning to Rank Challenge* [13], the Yandex Internet Mathematics competition<sup>2</sup>, the LETOR [40] dataset and the LETOR successors MSLR-WEB10k and MSLR-WEB30k.

#### THESIS OVERVIEW

- PART II: BACKGROUND introduces the reader to the basic principles and recent work in the fields of Learning-to-Rank.
- PART III: RELATED WORK concisely describes existing work in the field of parallel machine learning and parallel Learning-to-Rank.
- PART IV: BENCHMARK RESULTS sketches the performance of existing Learning-to-Rank methods on several benchmark datasets and describes the selection of Learning-to-Rank methods for the parallelisation experiments.
- PART V: SELECTED LEARNING-TO-RANK METHODS describes the algorithms and details of the selected Learning-to-Rank methods.
- PART VI: IMPLEMENTATION describes implementation details of the Learning-to-Rank algorithms in the Hadoop framework.
- PART VII: RESULTS & DISCUSSION presents and discusses speed-up results for the implemented Learning-to-Rank methods.
- PART VIII: CONCLUSION summarizes the results and answers our research questions based on the results. The limitations of our research as well as future research directions in the field are mentioned here.

# Part II

# TECHNICAL BACKGROUND

This part provides a background in the Learning-to-Rank field with the goal of making the subsequential parts of this thesis understandable for non-experts in the field.

Different definitions of Learning-to-Rank exist. In general, all ranking methods that use machine learning technologies to solve the problem of ranking are called Learning-to-Rank methods. Figure 1 describes the general process of machine learning. It shows training elements from an input space that are mapped to an output space using a model such that the difference between the actual labels of the training elements and the labels predicted with with the model are minimal in terms of a loss function.

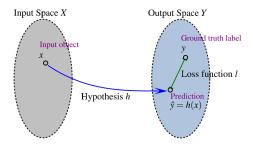

Figure 1: Machine learning framework for Learning-to-Rank, obtained from Liu [30]

Liu [30] proposes a more narrow definition and only considers ranking methods to be a Learning-to-Rank method when it is *feature based* and uses *discriminative training*, which are itself defined as follows:

FEATURE BASED means that all documents under investigation are represented by feature vectors that reflect the relevance of the documents to the query.

be well described by the four components of discriminative learning. That is, a Learning-to-Rank method has its own *input space*, *output space*, *hypothesis space*, and *loss function*, like the machine learning process described by Figure 1. *Input space*, *output space*, *hypothesis space*, and *loss function* are hereby defined as follows:

INPUT SPACE contains the objects under investigation. Usually objects are represented by feature vectors, extracted according to different applications.

OUTPUT SPACE contains the learning target with respect to the input objects.

HYPOTHESIS SPACE defines the class of functions mapping the input space to the output space. The functions operate on

the feature vectors of the input object, and make predictions according to the format of the output space.

LOSS FUNCTION in order to learn the optimal hypothesis, a training set is usually used, which contains a number of objects and their ground truth labels, sampled from the product of the input and output spaces.

Figure 2 shows how the machine learning process as described in Figure 1 typically takes place in a ranking scenario. A set of queries  $q_i$  with n > i > 1, the documents associated with these queries which are represented by feature vector  $x_i$ , and the relevant judgements of those documents  $y_i$  are used together to train a model h. Model h can after training be used to predict a ranking of the documents  $y_i$ , such the difference between the document rankings predicted by h and the actual optimal rankings based on  $y_i$  is are minimal in terms of a loss function.

Figure 2: A typical Learning-to-Rank setting, obtained from Liu [30]

The predictions and the loss function might either be defined for:

- 1. the relevance of a single document
- 2. the classification of the most relevant document out of a documentpair
- 3. the ranking of documents directly

These three approaches are in literature respectively called the pointwise approach, the pairwise approach and the listwise approach. These three approaches to Learning-to-Rank will be described in more detail further on in this part.

#### EVALUATING A RANKING

Evaluation metrics have long been studied in the field of information retrieval. First in the form of evaluation of unranked retrieval sets and later, when the information retrieval field started focussing more on ranked retrieval, in the form of ranked retrieval evaluation. In the succeeding section several frequently used evaluation metrics for ranked results will be described.

No single evaluation metric that we are going to describe is indisputably better or worse than any of the other metrics. Different benchmarking settings have used different evaluation metrics. Metrics introduced in this section will be used to express the evaluation results in the Benchmark Results part of this thesis.

#### 6.1 NORMALIZED DISCOUNTED CUMULATIVE GAIN

Cumulative gain, or its predecessor discounted cumulative gain and normalized discounted cumulative gain, is one of the most widely used measures for effectiveness of ranking methods.

#### 6.1.1 Discounted Cumulative Gain

The Discounted Cumulative Gain (DCG) [7] at a position p is defined as

$$DCG_p = \sum_{i=1}^p \frac{2^{rel_i-1}}{\log_2(i+1)}$$

with  $rel_i$  the graded relevance of the result at position i. The idea is that highly relevant documents that appear lower in a search result should be penalized (discounted). This discounting is done by reducing the graded relevance logarithmically proportional to the position of the result.

#### 6.1.2 Normalized Discounted Cumulative Gain

nDCG normalizes the DCG metric to a value in the [0,1] interval by dividing by the DCG value of the optimal rank. This optimal rank is obtained by sorting documents on relevance for a given query. The definition of nDCG can be written down mathematically as

	Rank										
	1	2	3	4	5	6	7	8	9	10	Sum
rel(i)	10	7	6	8	9	5	1	3	2	4	
$\frac{2^{\operatorname{rel}_{i}-1}}{\log_{2}(i+1)}$	512	40.4	16	55.1	99.0	5.7	0.3	1.3	0.6	2.3	732.7
optimal rank	10	9	8	7	6	5	4	3	2	1	
$\frac{2^{\operatorname{rel}_{i}-1}}{\log_{2}(i+1)}$	512	161.5	64	27.6	12.4	5.7	2.7	1.3	0.6	0.2	788.o

$$nDCG = \frac{732.7}{788.0} = 0.93$$

Table 1: Example calculation for nDCG

$$n\mathsf{DCG}_{\mathfrak{p}} = \tfrac{\mathsf{DCG}_{\mathfrak{p}}}{\mathsf{IDCG}_{\mathfrak{p}}}$$

Table 1 shows an example calculation for nDCG.

#### 6.2 EXPECTED RECIPROCAL RANK

Expected Reciprocal Rank (ERR) [15] was designed based on the observation that nDCG is based on the false assumption that the usefulness of a document at rank i is independent of the usefulness of the documents at rank less than i. ERR is based on the reasoning that users are likely to stop exploring the result list once they have found a document that satisfied their information need. The ERR metric is defined as the expected reciprocal length of time that the user will take to find a relevant document. ERR is formally defined as

$$ERR = \sum_{r=1}^{n} \frac{1}{r} \prod_{i=1}^{r-1} (1 - R_i) R_i$$

where the product sequence part of the formula represents the chance that the user will stop at position r.

An algorithm to compute ERR is shown in Listing 1. The algorithm requires relevance grades  $g_i$ ,  $1 \le i \le n$  and mapping function R that maps relevance grades to probability of relevance.

Listing 1: Algorithm to compute the ERR metric, obtained from [15]

	Rank									Sum		
	1	2	3	4	5	6	7	8	9	10		
$r_i$	1	o	o	O	1	1	O	1	O	0		
P@i	1				0.4	0.5		0.5				2.4
										/#Relevant docs	=	7
										AP@10	=	0.34

Table 2: Average Precision example calculation. The number of relevant documents *R* is assumed to be seven.

### 6.3 MEAN AVERAGE PRECISION

Average Precision (AP) [64] is an often used binary relevance judgement based metric that can be seen as a trade-off between precision and recall that is defined as

$$AP = \frac{\sum_{k=1}^{n} Precision(k) * relevance(k)}{number \ of \ relevant \ docs}$$

With k being the positions in the result set between 1 and n. Table 2 provides an example calculation of average precision where de documents at positions 1, 5, 6 and 8 in the ranking are relevant. MAP is the average AP for a set of queries.

$$MAP = \frac{\sum_{q=1}^{Q} AP(q)}{Q}$$

#### APPROACHES TO LEARNING-TO-RANK

#### 7.1 POINTWISE APPROACH

The pointwise approach can be seen as the most straightforward way of using machine learning for ranking. Pointwise Learning-to-Rank methods directly apply machine learning methods to the ranking problem by observing each document in isolation. They can be subdivided in the following approaches:

- 1. regression-based, which estimate the relevance of a considered document using a regression model.
- 2. classification-based, which classify the relevance category of the document using a classification model.
- 3. ordinal regression-based, which classify the relevance category of the document using a classification model in such a way that the order of relevance categories is taken into account.

#### 7.2 PAIRWISE APPROACH

Pointwise Learning-to-Rank methods have the drawback that they optimise real valued expected relevance, while evaluation metrics like nDCG and ERR are only impacted by a change in expected relevance when that change impacts a pairwise preference. The pairwise approach solves this drawback of the pointwise approach by regarding ranking as pairwise classification. Aggregating a set of predicted pairwise preferences into the corresponding optimal rank is shown to be a NP-Hard problem.

#### 7.3 LISTWISE APPROACH

Listwise ranking optimises the actual evaluation metric. The learner learns to predict an actual ranking itself without using an intermediate step like in pointwise or pairwise Learning-to-Rank. The main challenge in this approach is that most evaluation metrics are not differentiable. MAP, ERR and nDCG are all discontinuous and non-convex functions, what makes them very hard to optimize.

# Part III RELATED WORK

#### RELATED WORK

The literature research is performed by using the bibliographic databases Scopus and Web of Science with the following search query: ("learning to rank" OR "learning-to-rank" OR "machine learned ranking") AND ("parallel" OR "distributed"). An abstract based manual filtering step is applied where I filter those results that actually use the parallel or distributed terms in context to the learning to rank, learning-to-rank or machine learned ranking. Studies focusing on efficient query evaluation instead of efficient model training are likely to meet all criteria listed. As a last step I will filter out studies based on the whole document that only focus on efficient query evaluation and not on parallel or distributed learning of ranking functions.

on Scopus the defined search query resulted in 65 documents. Only 14 of those documents used *large scale*, *parallel* or *distributed* terms in context to the *learning to rank*, *learning-to-rank* or *machine learned rank-ing*. 10 out of those 14 documents focussed on parallel or distributed learning of ranking functions.

The defined search query resulted in 16 documents on Web of Science. Four of those documents were also present in the set of 65 documents found using Scopus, leaving 61 unique documents. Only four of those 61 documents used *large scale*, *parallel* or *distributed* terms in context to the *learning to rank*, *learning-to-rank* or *machine learned ranking*, none of them focussed on parallel or distributed learning of ranking functions.

On Google Scholar the defined search query resulted in 3300 documents. We evaluate the first 300 search results.

The following sections describe the literature study results found.

#### 8.1 CCRANK

Wang et al. [51, 52] propose a parallel evolutionary algorithm based on Cooperative Coevolution (CC), a type of evolutionary algorithm. The CC algorithm is capable of directly optimizing non-differentiable functions, as nDCG, in contrary to many optimization algorithms. the divide-and-conquer nature of the CC algorithm enables parallelisation. CCRank showed an increase in both accuracy and efficiency on the LETOR 4.0 benchmark dataset compared to the baselines. It

must be stated however that the increased efficiency was achieved through speed-up and not scale-up. Two reasons have been identified for not achieving linear scale-up with CCRank: 1) parallel execution is suspended after each generation to perform combination in order to produce the candidate solution, 2) Combination has to wait until all parallel tasks have finished, which may spend different running time.

#### 8.2 PARALLEL LISTNET USING SPARK

Shukla et al. [43] explored the parallelisation of the well-known List-Net Learning-to-Rank method using Spark. Spark is a parallel computing model that is designed for cyclic data flows which makes it more suitable for iterative algorithms. Spark is incorporated into Hadoop since Hadoop 2.o. The Spark implementation of ListNet showed near a linear training time reduction.

#### 8.3 GRADIENT BOOSTED DISTRIBUTED DECISION TREES

Ye et al. [60] described how to implement the Gradient Boosted Decision Tree (GBDT) process in a parallel manner using both MPI and Hadoop. GBDT's are shown to be able to achieve good accuracy in a Learning-to-Rank setting when used in a pairwise [63] or listwise [16] setting. Experiments showed the Hadoop implementation to result into too expensive communication cost to be useful. Authors believed that these high communication costs were a result of the communication intensive implementation that was not well suited for the MapReduce paradigm. The MPI approach proved to be successful and obtained near linear speed-ups.

#### 8.4 NDCG-ANNEALING

Karimzadeghan et al. [27] proposed a method using Simulated Annealing along with the Simplex method for its parameter search. This method directly optimises the often non-differentiable Learning-to-Rank evaluation metrics like nDCG and MAP. The authors successfully parallelised their method in the MapReduce paradigm using Hadoop. The approach showed to be effective on both the LETOR 3.0 dataset and their own dataset with contextual advertising data. Unfortunately their work does not directly report on the speed-up obtained by parallelising with Hadoop, but it is mentioned that further work needs to be done to effectively leverage parallel execution.

#### 8.5 LOW COMPLEXITY LEARNING-TO-RANK

Designing Learning-to-Rank algorithms with low time complexity for training is another approach towards large scale Learning-to-Rank. Pahikkala et al. [37] describe a pairwise Regularised Least-Squares (RLS) type of ranking function, RankRLS, with time complexity  $\mathcal{O}(n^3 + n^2m)$ , with n the number of features and m the number of training documents. The RankRLS ranking function showed ranking performance similar to RankSVM on the BioInfer corpus [39], a corpus for information extraction in the biomedical domain.

#### 8.6 DISTRIBUTED STOCHASTIC GRADIENT DESCENT

Long et al. [32] describe special case of their pairwise cross-domain factor Learning-to-Rank method using distributed optimization of Stochastic Gradient Descent (SGD) based on Hadoop MapReduce. Parallelisation of the SGD optimization algorithm was performed using the MapReduce based method described by Zinkevich et al. [65] has been used. Real world data from Yahoo! has been used to show that the model is effective. Unfortunately the speed-up obtained by training their model in parallel is not reported.

#### 8.7 FPGA-BASED LAMBDARANK

Yan et al. [56, 57, 58, 59] described the development and incremental improvement of a Single Instruction Multiple Data (SIMD) architecture Field-Programmable Gate Array (FPGA) designed to run the Neural Network based LambdaRank Learning-to-Rank algorithm. This architecture achieved a 29.3X speed-up compared to the software implementation when evaluated on data from a commercial search engine. The exploration of FPGA for Learning-to-Rank showed other advantages of the FPGA approach next to faster model training. In their latest publication [59] the FPGA based LambdaRank implementation showed it could achieve up to 19.52X power efficiency and 7.17X price efficiency for query processing compared to Intel Xeon servers currently used at the commercial search engine.

#### 8.8 GPGPU FOR LEARNING-TO-RANK

De Sousa et al. [19] proposed a General-Purpose computing on Graphical Processing Units (GPGPU) approach using the Graphical Processing Unit (GPU) both learning the ranking function and for query processing, thereby improving both training time and query time. An association rule based Learning-to-Rank approach proposed by [50] has been implemented using the GPU in such a way that the set of rules van be computed in parallel, in different threads, for each docu-

ment. A speed-up of 127X in query processing time is reported based on evaluation on the LETOR dataset. The speed-up achieved at learning the ranking function was unfortunately not stated.

#### 8.9 BAGBOO: A HYBRID BAGGING-THE-BOOSTING MODEL

Pavlov et al. [38] at Yandex developed a hybrid model that combines two methods from ensemble learning: bagging and boosting. Bagging [6], also called bootstrap aggregating, is a ensemble learning method in which m training sets  $D_1...D_m$  are constructed from the training set D by uniformly sampling data items from D with replacement. The bagging method is parallelisable by training each  $D_i$  with  $i \in \{1...m\}$  on a different node. Boosting [23] is an ensemble learning method in which multiple weak learners are iteratively added together into one ensemble model in such a way that new models focus more on those data instances that were misclassified before. Boosting is not parallelisable, but the authors state that learning a short boosted sequence on a single node is still a do-able task.

#### 8.10 BOOSTINGTREE

Kocsis et al. [28] propose way to train multiple weak learners in parallel and extend those models that are likely to yield a good model when combined through boosting. Authors showed through theoretical analysis that the proposed algorithm asymptotically achieve equal performance to regular boosting. Using this parallel BoostingTree algorithm GBDT models could be trained in parallel.

#### 8.11 DEEP STACKING NETWORKS

A Deep Stacking Network (DSN) is a processing architecture developed from the field of *Deep Learning*, that uses the Mean Squared Error (MSE) loss function that is easily optimisable. DSN is based on the stacked generalization ensemble learning method [53], an approach where several learning models are stacked on top of each other in such a way that the output of a model is used as one of the input features of models higher up in the stack. Each layer in the stack learns has the task of learning the weights of the inputs of that layer. The close-form constraints between input and output weights allow the input weight matrices to be estimated in a parallel manner.

#### 8.12 ALTERNATING DIRECTION METHOD OF MULTIPLIERS

Duh et al. [21] propose the use of Alternating Direction Method of Multipliers (ADMM) for the Learning-to-Rank task. ADMM is a general optimization method that solves problems of the form

```
minimize f(x) + g(x)
subject to Ax + Bz = c
```

by updating x and z in an alternating fashion. It holds the nice properties that it can be executed in parallel and that it allows for incremental model updates without full retraining. Duh et al. [21] show how to use ADMM to train a RankSVM model in parallel. Experiments showed the ADMM implementation to achieve a 13.1x training time speed-up on 72 workers, compared to training on a single worker.

Another ADMM Learning-to-Rank based approach was proposed by Boyd et al. [5]. Boyd et al. [5] implemented an ADMM based Learning-to-Rank method in Pregel [34], a parallel computation framework for graph computations. No experimental results on parallelisation speed-up were reported on this Pregel based approach.

# 8.13 DISTRIBUTED HYPER-PARAMETER TUNING USING MAPREDUCE

Ganjisaffar et al. [24] observed that long training times are often a result of training many models for hyperparameter optimisation. Grid search is the *de facto* standard of hyperparameter optimisation and is simply an exhaustive search through a manually specified subset of hyperparameter combinations. The authors show how to perform parallel grid search on MapReduce clusters, which is easy because grid search is an embarrassingly parallel method as hyperparameter combinations are mutually independent. They apply their grid search on MapReduce approach in a Learning-to-Rank setting to train a LambdaMART [54] ranking model, a model that uses the Gradient Boosting [23] ensemble method combined with regression tree weak learners. Experiments showed that the solution scales linearly in number of hyperparameter combinations. However, the risk of overfitting grows overwhelmingly as the number of hyperparameter combinations grow, even when validation sets grow large.

#### 8.14 DISTRIBUTED LAMBDARANK

Svore and Burges [48, 47] designed two approaches to train the LambdaMART [54] model in a distributed manner. Their first approach is applicable in case the whole training set fits in main memory on every node, in that case the tree split computations of the regressions

trees in the LambdaMART tree ensemble are split and the data is not. The second approach distributes the training data and corresponding training computations and is therefore scalable to high amounts of training data. Both approaches achieves a six times speed-up over LambdaMART on 32 nodes compared to a single node.

# 8.15 LEARNING-TO-RANK WITH BREGMAN DIVERGENCES AND MONOTONE RETARGETING

Acharyya et al. [1] propose a Learning-to-Rank method searches for an order preserving transformation (*monotone retargeting*) of the target scores that is easier for a regressor to fit. This approach is based on the observation that it is not necessary to fit scores exactly, since the evaluation is dependent on the order and not on the pointwise predictions themselves.

Bregman divergences are a family of distance-like functions that do not satisfy symmetry nor the triangle inequality. A well-known member of the class of Bregman divergences is Kullback-Leibler divergence, also known as *information gain*.

Acharyya et al. [1] defined a parallel algorithm that optimises a Bregman divergence function as surrogate of nDCG that is claimed to be well suited for implementation of a GPGPU. No experiments on speed-up have been performed.

### Part IV

# BENCHMARK RESULTS

This part describes benchmark characteristics like collection size and features and gives an overview of the performance of different Learning-to-Rank methods. Performance differences for a given Learning-to-Rank method are explained in terms of differences in benchmark characteristics. This section is concluded with a selection of Learning-to-Rank methods to include in the experiments.

#### YAHOO! LEARNING TO RANK CHALLENGE

Yahoo's observation that all existing benchmark datasets were too small to draw reliable conclusions prompted Yahoo to release two internal datasets from Yahoo! search. Datasets used at commercial search engines are many times larger than available benchmark datasets. Yahoo! published a subset of their own commercial training data and launched a Learning-to-Rank competition based on this data. The Yahoo! Learning to Rank Challenge [13] is a public Learning-to-Rank competition which took place from March to May 2010, with the goal to promote the datasets and encourage the research community to develop new Learning-to-Rank algorithms.

The Yahoo! Learning to Rank Challenge consists of two tracks that uses the two datasets respectively: a standard Learning-to-Rank track and a transfer learning track where the goal was to learn a specialized ranking function that can be used for a small country by leveraging a larger training set of another country. For this experiment, I will only look at the standard Learning-to-Rank dataset, because transfer learning is a separate research area that is not included in this thesis.

	Train	Validation	Test
Queries	19,994	2,994	6,983
Documents	473,134	71,083	165,660
Features	519	-	-

Table 3: Yahoo! Learning to Rank Challenge dataset characteristics, as described in the challenge overview paper [13]

Both nDCG and ERR are measured as performance metrics, but the final standings of the challenge were based on the ERR values. Model validation on the Learning-to-Rank methods participating in the challenge is performed using a train/validation/test-set split following the characteristics shown in Table 3. Competitors could train on the training set and get immediate feedback on their performance on the validation set. The test set performance is used to create the final standings and is only measured after the competition has ended to avoid overfitting on the test set. The large number of documents, queries and features compared to other benchmark datasets makes the Yahoo! Learning to Rank Challenge dataset interesting. Yahoo did not provide detailed feature descriptions to prevent competitors to get detailed insight in the characteristics of the Yahoo data collec-

tion and features used at Yahoo. Instead high level descriptions of feature categories are provided. The following categories of features are described in the challenge overview paper [13]:

- WEB GRAPH Quality and popularity metrics of web documents, e.g. PageRank [36].
- DOCUMENT STATISTICS Basic document statistics such as the number of words and url characteristics.
- DOCUMENT CLASSIFIER Results of various classifiers on the documents. These classifiers amongst others include: spam, adult, language, main topic, and quality classifiers.
- QUERY Basic query statistics, such as the number of terms, query frequency, and click-through rate.
- TEXT MATCH Textual similarity metrics between query and document. Includes Term Frequency Inverse Document Frequency (TF-IDF), BM25 [41] and other metrics for different sections of the document.
- TOPICAL MATCHING These features go beyond similarity at word level and compute similarity on topic level. For example by classifying both the document and the query in a large topical taxonomy.
- CLICK Click-based user feedback.
- EXTERNAL REFERENCES Document meta-information such as Delicious<sup>1</sup> tags
- TIME Document age and historical in- and outlink data that might help for time sensitive queries.

#### 9.1 RESULTS

Figure 4 shows the top five participants in the Yahoo! Learning to Rank Challenge in terms of ERR score. The top five participants all used decision trees and ensemble methods. Burges et al [9] created a linear combination ensemble of eight LambdaMART [8], two LambdaRank and two Logistic Regression models. Gottschalk and Vogel used a combination of RandomForest models and GBDT models. Pavlov and Brunk used a regression based model using the Bag-Boo [38] ensemble technique, which combines bagging and boosting. Sorokina used a similar combination of bagging and boosting that is called Additive Groves [44].

<sup>1</sup> https://delicious.com/

	Authors	ERR	
1	Burges et al (Microsoft Research)	0.46861	
2	Gottschalk (Activision Blizzard) & Vogel (Data Mining Solutions)	0.46786	
3	Parakhin (Microsoft)	0.46695 0.46678	
4	Pavlov & Brunk (Yandex Labs) o.a		
5	Sorokina (Yandex Labs) 0.46616		

Table 4: Final standings of the Yahoo! Learning to Rank Challenge, as presented in the challenge overview paper [13]

The challenge overview paper states as one of the lessons of the challenge that the simple baseline GBDT model performed very well with a small performance gap to the complex ensemble submissions at the top of the table.

Although the winning GBDT models performs very well in terms of nDCG their high complexity makes them unsuitable to use in production. The winning models take weeks to train and are very slow during query evaluation. An exception in training time is the BagBoo [38] method used by Pavlov & Brunk. The bagging component of the BagBoo method enables it to achieve high scalability through parallelism. Pavlov et al [38] managed to train half a million trees on 200 nodes in 2 hours.

10

# YANDEX INTERNET MATHEMATICS COMPETITION

10.1 RESULTS

The Yandex Internet Mathematics competition was won by Pavlov et al [38] with the BagBoo method.

#### LETOR

The LETOR benchmark set was first released by Microsoft Research Asia in April 2007 to solve the absence of a experimental platform for Learning-to-Rank at that time. LETOR has been updated several times since: LETOR 2.0 was released at the end of 2007, LETOR 3.0 in December 2008 and LETOR 4.0 in July 2009. The LETOR3.0 benchmark collection [31] as released in 2007 contained two data sets: the OHSUMED collection and the .gov collection.

#### 11.1 LETOR3.0

The OHSUMED collection is a subset of the medical publication database MEDLINE and contains medical publications from 270 journals that were published between 1987 and 1991. The .gov collection is a web crawl obtained in January 2002, which was used for the TREC web track in 2003 and 2004. Tables 5 and 6 provide the descriptions of the features of the .gov and the OHSUMED collections respectively.

Different query sets exists for the .gov corpus. Those query sets are categorized in the following categories [18]:

- TOPIC DISTILLATION (TD) these queries involve finding relevant pages given a broad query. E.g., the query 'cotton industry' which is entered with the aim to find pages that provide information about the cotton industry.
- NAMED PAGE FINDING (NP) in these queries the user asks for one specific page by name. E.g., the user queries for 'ADA Enforcement' to find the page http://www.usdoj.gov/crt/ada/enforce.htm.
- HOME PAGE FINDING (HP) these queries are similar to NP queries in that the user is looking for one specific page, but now this specific page is a homepage. E.g., the user queries for 'Tennessee Valley Authority' to find the homepage http://www.tva.gov.

With query sets available from both the TREC 2003 and 2004 conferences there are six query sets in total: TD2003, TD2004, NP2003, NP2004, HP2003 and HP2004.

The evaluation metrics used are nDCG and MAP. The *winning number* metric is defined as the number of other algorithms that it can beat over all of the seven datasets (six .gov sets + OHSUMED). The

LETOR organisation implemented and evaluated several well-known Learning-to-Rank algorithms themselves and in addition gathers and publications and results of new algorithms evaluated on the LETOR benchmark. The baseline Learning-to-Rank algorithms evaluated by the organisation are:

#### **POINTWISE**

• Linear regression

#### **PAIRWISE**

- RankingSVM [25, 26]
- RankBoost [22]
- FRank [49]

#### LISTWISE

- ListNet [11]
- AdaRank-MAP [55]
- AdaRank-nDCG [55]
- SVMMAP [61]

#### 11.1.1 Results

The LETOR paper [40] describes the performance of the LETOR base-line methods. Figures 3 and 4 show ListNet to be the best performing baseline in terms of winning number on both nDCG and MAP. The LETOR website lists<sup>1</sup> a few algorithms that have since been evaluated on the LETOR benchmark collection.

Figure 3: Comparison across the seven datasets in LETOR by nDCG, obtained from Qin et al [40]

Table 6: Features of the LETOR OHSUMED dataset, obtained from Qin et al [40]

with the ListNet baseline. We will consider those methods to be better than ListNet when they beat the ListNet baseline in at least four of the seven datasets in nDCG value. Note that this does not necessarily imply that these methods would have scored a higher nDCG winning number than ListNet. Table 7 shows the ListNet performance on the seven LETOR datasets in terms of nDCG@10 and MAP.

	nDCG@10	MAP
TD2003	0.348	0.2753
TD2004	0.317	0.2231
NP2003	0.801	0.6895
NP2004	0.812	0.6720
HP2003	0.837	0.7659
HP2004	0.784	0.6899
OHSUMED	0.441	0.4457

Table 7: Performance of ListNet on LETOR

Table 8: Comparison of algorithms recently evaluated on LETOR3.0 with the ListNet baselines

Figure 4: Comparison across the seven datasets in LETOR by MAP, obtained from Qin et al [40]

#### 11.2 LETOR4.0

#### 11.2.1 Results

BoostedTree model [28] showed an nDCG of 0.5071 on the MQ2007 dataset and thereby beat all baseline models.

#### MSLR-WEB10K/MSLR-WEB30K

Contrary to the Yahoo! Learning to Rank Challenge dataset, the MSLR-WEB30k provides detailed feature descriptions. The MSLR-WEB30k dataset however contains no proprietary features but only features that are commonly used in the research community.

12.1 RESULTS

#### SELECTING LEARNING-TO-RANK METHODS

The Accuracies of the Learning-to-Rank methods described in the preceding chapters must only be compared within the benchmark and not between benchmarks for the following reasons:

- 1. Differences in feature sets between data sets detract from fair comparison
- 2. Although the nDCG definition is unambiguous, Busa-Fekete et al [10] found that nDCG evaluation tools of benchmark data sets produced different scores

#### Part V

## SELECTED LEARNING-TO-RANK METHODS

Algorithms and details of the well-performing Learning-to-Rank methods as selected in the aforegoing part are presented and explained in this part.

#### Part VI

#### **IMPLEMENTATION**

Describes implementation details of the Learning-to-Rank algorithm parallel implementations in HDInsight that are either Hadoop, Microsoft Azure, or HDInsight and are not part of the algorithm specification itself.

# Part VII RESULTS & DISCUSSION

# Part VIII

CONCLUSIONS

# Part IX

#### COLOPHON

This document was typeset using the typographical look-and-feel classicthesis developed by André Miede. The style was inspired by Robert Bringhurst's seminal book on typography "The Elements of Typographic Style". classicthesis is available for both LATEX and LyX:

http://code.google.com/p/classicthesis/

Happy users of classicthesis usually send a real postcard to the author, a collection of postcards received so far is featured here:
